A Key for the Forest Service Hardwood Tree Grades

Gary W. Miller, Leland F. Hanks, and Harry V. Want, Jr.

ABSTRACT: A dichotomous key organizes the USDA Forest Service hardwood tree grade specifications into a stepwise procedure for those learning to grade hardwood sawtimber. The key addresses the major grade factors, tree size, surface characteristics, and allowable curl deductions. It outlines a series of paired choices that lead the user to a decision regarding tree grade. Subtle grading rules, previously presented as footnotes to the major specifications, are included in the key. It simplifies the process so that the beginner can learn the system quickly, without detailed instruction from experienced tree graders.

USDA Forest Service hardwood tree grades are used to predict factory lumber grade yields for many commercial hardwood species. The grading system makes it possible to calculate the dollar value of standing timber from the grades and prices of lumber that can be sawn from individual trees. Once familiar with the system, timber graders can provide consistent estimates of timber quality and stand value. The key presented in this paper serves as a teaching aid for those learning to grade hardwood trees. It provides a stepwise procedure for determining the grades of individual trees and organizes the grade specifications so that the beginner is not overwhelmed with choices (Table 1).

Many people find it difficult to learn the tree grading system using existing references, especially when experienced graders are not available to provide detailed instruction. The key overcomes these major problems beginners often encounter when trying to learn tree grading from earlier presentations. First, the key contains the

noble grade specifications previously presented as footnotes to the major grade factors. This improvement makes the beginner aware of the fine points without disrupting the step-by-step process of grading. Second, the key addresses the grade factors in a sequence that reduces confusion and improves comprehension. Third, the key can be used to learn how to grade hardwood trees without detailed instruction. Field trials have indicated that beginners can use the key to determine the correct tree grade, while those using other references require outside help. This feature of the key allows the beginner to be competent without the delays and costs associated with more formal training. As a result, tree grades can be used to assess tree quality and value in a shorter period of time.

BACKGROUND

The most difficult part of tree grading is recognizing defect indicators on the surface of the tree. Photographic guides are available for some commercial species. Estimating interior curl deductions is also difficult for the beginner. References are available for making adjustments for sweep, crook, and rot. In addition to learning the grade specifications, the trainee should use and review these references to maintain competence in all aspects of grading and scaling.

TREE GRADE SPECIFICATIONS

Tree grade is generally determined by characteristics of the best 12-ft grading section in the butt 16-ft log. A 14- or 16-ft grading section may be used if it results in a better grade than the 12-ft section. Field experience with Forest Service tree grades has shown that tree grade is usually defined by characteristics of the bottom 12-ft section or the top 12-ft section in the butt log. Occasionally, however, using a 14- or 16-ft grading section results in a higher grade. A simple rule is to use the grading section that results in the highest tree grade.

Forest Service tree grade specifications involve three major characteristics of the grading section:

1. Minimum dbh of 12.6 inches (14.6 inches for hardwood and ash) ........................................ 2
2. Minimum dbh of 9.6 inches (if dbh is less than 9.6 inches stop here; tree is below grade) .... 18
3. Clear cuttings total at least 10 feet in 1 or 2 cuttings — each cutting at least 7 feet long 5
4. Clear cuttings total less than 10 feet in 1 or 2 cuttings — each cutting at least 7 feet long 3
5. Clear cuttings total less than 10 feet in 1 or 2 cuttings — each cutting at least 7 feet long (due to rot only) 15
6. Clear cuttings total at least 10 feet in 1 or 2 cuttings — each cutting at least 5 feet long 6
7. Clear cuttings total less than 10 feet in 1 or 2 cuttings — each cutting at least 5 feet long 4
8. Clear cuttings total less than 10 feet in 1 or 2 cuttings — each cutting at least 5 feet long (due to rot only) 15
9. Clear cuttings total at least 10 feet in 1 or 2 cuttings — each cutting at least 3 feet long 7
10. Clear cuttings total less than 10 feet in 1 or 2 cuttings — each cutting at least 3 feet long 11
11. Clear cuttings total less than 10 feet in 1 or 2 cuttings — each cutting at least 3 feet long (due to rot only) 15
12. Clear cuttings total at least 12.6 inches (11.6 inches for hardwood and ash) ............... 8
13. Clear cuttings total less than 15.6 inches ................................. 8
14. Clear cuttings total less than 15.6 inches (due to rot only) ....................... 17
15. Clear cuttings total at least 15.6 inches ................................. 8
16. Clear cuttings total less than 15.6 inches (due to rot only) ....................... 17
17. Clear cuttings total at least 19.6 inches ................................. 8
18. Clear cuttings total less than 19.6 inches (due to rot only) ....................... 17
19. Total call deduction, including sweep, crook, and rot does not exceed 9% ........... GRADE 1
20. Total call deduction exceeds 9% ............................................................................. 9
21. Cell deduction does not exceed 15% for sweep and crook, and total call deduction does not exceed 40% GRADE 2
22. Cell deduction for sweep and crook exceeds 15% or total call deduction exceeds 40% 20
23. Clear cuttings total at least 10 feet in 1 or 2 cuttings — each cutting at least 3 feet long 17
24. Clear cuttings total less than 10 feet in 1 or 2 cuttings — each cutting at least 3 feet long 11
25. Clear cuttings total at least 8 feet in 1 or 2 cuttings — each cutting at least 3 feet long 13
26. Clear cuttings total less than 8 feet in 1 or 2 cuttings — each cutting at least 3 feet long 12
27. Clear cuttings total at least 8 feet in 1, 2, or 3 cuttings — each cutting at least 3 feet long 14
28. Clear cuttings total less than 8 feet in 1, 2, or 3 cuttings — each cutting at least 3 feet long 18
29. Clear cuttings total at least 8 feet in 1, 2, or 3 cuttings — each cutting at least 3 feet long (due to rot only) 16
30. Clear cuttings total less than 8 feet in 1, 2, or 3 cuttings — each cutting at least 3 feet long (due to rot only) 18
31. Clear cuttings total at least 8 feet in 1, 2, or 3 cuttings — each cutting at least 3 feet long 16
32. Clear cuttings total less than 8 feet in 1, 2, or 3 cuttings — each cutting at least 3 feet long 18
33. Cell deduction for rot does not exceed 40% ................................................. GRADE 2
34. Cell deduction for rot exceeds 40% ..................................................................... 20
35. Cell deduction, including sweep, crook, and rot does not exceed 9% ........... GRADE 2
36. Cell deduction exceeds 9% ............................................................................. 20
37. Total call deduction exceeds 9% ........................................................................... 20
38. Clear cuttings total at least 6 feet, all cuttings at least 2 feet long ....................... 19
39. Clear cuttings total less than 6 feet, all cuttings at least 2 feet long ................. 19
40. Clear cuttings total at least 6 feet, all cuttings at least 2 feet long (due to rot only) 20
41. Clear cuttings total less than 6 feet, all cuttings at least 2 feet long (due to rot only) 20
42. Total call deduction, including sweep, crook, and rot does not exceed 50% ......... BELOW GRADE
43. Total call deduction exceeds 50% ..................................................................... BELOW GRADE
(1) size — diameter breast height (dbh) and diameter inside bark (dib) at the top of the grading section,
(2) clear cuttings — the total length of allowable clear cuttings on the second worst face of the grading section, and
(3) cull deductions — the percentage of volume deducted for sweep and crook and the percentage of volume deducted for sweep, crook, and rot combined.

As a tree is graded, each of these characteristics is examined to determine whether the tree qualifies for a particular grade. The key addresses each characteristic in a logical, stepwise procedure. In effect, the key systematically tests each characteristic until the tree is graded.

Size

Both dbh and dib at the top of the grading section must satisfy the minimum requirements of the assigned tree grade. The first step in determining tree grade is to measure dbh to the nearest inch. For grades 1, 2, and 3 the minimum dbh requirements are 16, 13, and 10 in, respectively. Dib at the top of the grading section, however, is the more important specification for determining grade. This is because dbh and another major tree grading characteristic, clear cuttings, are interrelated. Dib at the top of the grading section defines the minimum length or the maximum number of clear cuttings allowed in grades 1 and 2.

Since dbh at the top of the grading section cannot be measured directly, it must be estimated from dbh and an assigned form class. Recall that the top of the grading section can be 12, 14, or 16 ft above stump height. For a given dbh, dib will differ at 12, 14, and 16 ft above stump height because of taper. Tables 2 and 3 show the minimum dib required to meet the dib limitations for Girard form classes 79 and 82, respectively.

To use the tables, locate the appropriate dib limitation in the column of numbers at the left. Then find the position of the grading section across the top of the table. The number shown in the table is the minimum dib required to meet the dib limitation at that position. For example, the key indicates a minimum dib of 12.6 in for a tree that measures 15.8 in dbh. The top of the grading section is at 16 ft above stump height and form class is 79. Is the tree at least 12.6 in dbh at 16 ft above stump height? From Table 2, a tree of form class 79 must be at least 16.0 in dbh to have an inside bark diameter of 12.6 in at 16 ft above stump height. Dib at the top of the grading section is less than 12.6 in because the dbh of this particular tree is only 15.8 in.

NOTE: An alternative to this procedure is to utilize a device such as the Spiegel Rulerkop to directly measure the diameter outside bark (dob) at the top of the grading section. Once this value has been determined, it can be adjusted for bark thickness, by species, to determine dib at the top of the grading section.

Mathematically this relationship is:
dB = dbh - double bark thickness

Table 4 gives the double bark thicknesses for 9 hardwood species common to New York.

Clear Cuttings

To determine the total length of clear cuttings on the grading section, the first step is to identify the grading face of the tree. Visually square the butt log into four faces, using imaginary vertical lines. Arrange the faces so that the most defect indicators, such as bumps and knots, are concentrated on one face. The worst face is ignored, and the next-to-worst face becomes the grading face of the tree.

A clear cutting is a portion of the grading face that is free of defects and extends the width of the face. The grade specifications define the minimum length of clear cuttings, the maximum number of cuttings allowed, and the minimum total length of clear cuttings for each tree grade. Clear cuttings must total 5/6, 4/6, and 3/6 of the length of the grading face for grades 1, 2, and 3, respectively. The key assumes a 12-ft grading section. If a longer grading section is used, the minimum total length of clear cuttings should be adjusted according to Table 4.

Call Deductions

The key also defines maximum allowable deductions for sweep, crook, and rot. Figure 1 shows how most scaling deductions are determined. In calculating percent sweep deduction, the number subtracted from actual sweep varies with log length. When calculating percent deduction for sweep, the numerator is the sweep (in inches) minus 1.5 in for a 12-ft grading section and 2 in for a 14- or 16-ft grading section. Estimating internal rot requires good judgment and a lot of practice. The National Forest Log Scaling Handbook provides detailed instructions for estimating most scaling deductions.

USING THE KEY

Specific instructions on tree grading are presented in "Hardwood tree grades for factory lumber." The key simply organizes all the grade specifications and provides a stepwise procedure for the beginner. For each tree, start at the top of the key and proceed to the step indicated in the right-hand column of numbers. Continue following the key until the tree is graded. At first the beginner should rely on the key and consult Figure 1 to estimate scaling deductions. With more experience, grading can be done from memory.

Figure 1. Methods of determining scaling deductions (examples based on a 16-ft log with 20-in scaling diameter.)
Faces and Clear Cuttings

Face grading is used in the evaluation of the surface quality of a log. To accomplish this, the log is visually quartered into four faces in such a manner that the maximum number of defects is concentrated in as few faces as possible. Cuttings are then laid out between defects. Furthermore, these cuttings must be generally free from defects (except where otherwise specified). The grade of the log is then determined by the percentage yield of the prescribed number and size of cuttings (as shown in Appendix I) on the second poorest face.

Heart Center and Quality Zone*

The heart center when considered as the small end of the log, is taken as being a circle with a radius (from the pith) one-tenth of the average diameter. The quality zone, on the other hand, is that portion of the log outside the heart center. The quality zone is divided equally, in terms of radius, into the inner quality zone and the outer quality zone.

Sketch of log end to indicate zones used in log quality determination.

*Since the original printing of this report, the term, peripheral zone, has been replaced by quality zone, and the term periphery, as used in the text, has been replaced by outer quality zone. These changes have been made in this Appendix but not in the text.
